ABSTRACT

Glasses in the compositions $(Li_2O)_{25}-(BaO)_{25}-(P_2O_5)_{50-x}-(V_2O_5)_x$ (with $x=0.5, 1.0, 1.5, 2.0, 2.5$, and 3.0 mol %) have been prepared by the conventional melt quenching technique. X-ray powder diffractogram show broad peaks which conforms glassy nature of the sample. Differential scanning calorimetry (DSC) thermograms show characteristic glass transition temperature (T_g) and it increases with increasing substitution of V_2O_5 for P_2O_5 . The measured physical parameters like density, refractive index, ionic concentration and electronic polarizability are found to vary linearly with increasing x . Infrared spectra exhibits few bands, which are attributed to $(P=O)_AS$, $(P=O)_S$, $(V=O)$, $(P-O-P)_AS$, $P-O-V$, $(P-O-P)_AS$ and $O-P-O$ vibrations. The optical absorption spectra of VO^{2+} ions in these glasses show three bands and are assigned to the ${}^2B_2 \rightarrow {}^2E$, ${}^2B_2 \rightarrow {}^2B_1$ and ${}^2B_2 \rightarrow {}^2A_1$ transitions. Electron paramagnetic resonance spectra of all the glass samples exhibit resonance signals characteristic of VO^{2+} ions. The values of Spin-Hamiltonian parameters indicate that the VO^{2+} ions are present in octahedral sites with tetragonal compression and belong to C_{4v} symmetry.

1. Introduction

In general, phosphate glasses have a variety of technological applications due to their several unique properties such as high thermal expansion coefficient, low viscosity and high UV transmission [1]. Phosphate glasses doped with transitional metal (TM) ions are technologically important because of their semiconducting properties, optical absorption, electrical memory switching and photo-conducting properties. The properties that make phosphate glasses candidates for so many applications are related to their molecular-level structure [2–4]. A problem related to phosphate glasses containing TM oxides is related with their mixed dual role, as modifiers but also as network formers. It is demonstrated by means of Raman spectroscopy [5,6] that tungsten, iron or vanadium ions act as network modifiers but also as network formers depending by their concentration in the glass matrix [7]. Semiconducting transition metal oxide glasses have gained importance in recent years due to their possible applications in various technological fields [8,9]. Among such glasses, the vanadate glasses are being widely used in memory and switching devices [10]. V_2O_5 is known to participate in the glass network with VO_5 pyramidal structural units. Several vanadate glasses show

semiconducting behavior having electrical conductivity in the range of 10^{-3} – 10^{-5} ($\Omega\text{-cm}$) $^{-1}$, which is known to be due to small polaron hopping [11]. More precisely, vanadium containing glasses are identified as the n-type semiconductors for low value of the V^{4+}/V^{5+} ratio [11]. Electron paramagnetic resonance (EPR) yields information concerning valence state and local environment of implanted transition metal (TM) ions, as well as the nature of structural defects induced in the substrate by the implantation. EPR is also very sensitive to interactions among transition ions, and to the formation of both clusters and fine crystalline inclusions containing atoms of transition metals [12]. In the present investigation we have studied the structural changes that take place due to inter substitution of $V_2O_5 \leftrightarrow P_2O_5$ in phosphate barium lithium glass network using V_2O_5 as probing oxide. These structural changes are discussed with help of DSC, optical absorption, IR and EPR studies.

2. Experimental

2.1. Glass preparation

The nominal compositions of the glasses examined here and their designations are listed in Table 1. The glasses with compositions $(Li_2O)_{25}-(BaO)_{25}-(P_2O_5)_{50-x}-(V_2O_5)_x$ (with $x=0.5, 1.0, 1.5, 2.0, 2.5$, and 3.0 mol%) is chosen for the studies. The composition of the modifier

Table 1
Glass matrix with glass code.

Sample code	Mol (%)			
	Li ₂ O	BaO	P ₂ O ₅	V ₂ O ₅
V1	25	25	49.50	0.5
V2	25	25	49.00	1.0
V3	25	25	48.50	1.5
V4	25	25	48.00	2.0
V5	25	25	47.50	2.5
V6	25	25	47.00	3.0

in the glass system (Li₂O/BaO) is chosen in such a way that it avoids the hygroscopicity and extends the glass forming region. Analytical grade compounds of NH₄H₂PO₄, V₂O₅, Li₂CO₃ and BaCO₃ were used as starting materials. All the chemicals were weighed accurately, ground to fine powder and mixed thoroughly. The batches were melted at 1150 °C in a porcelain crucible by placing them in an electrical furnace. The melts were then poured on a polished brass plate and pressed quickly with another plate. The glasses thus obtained were transparent and greenish in color with the thickness of 1.5 mm. Samples were annealed at 200 °C in a furnace for 4 h, in order to relieve the thermal stresses. Finally, the samples were cooled naturally.

2.2. X-ray diffraction

The X-ray diffraction patterns of powder glass samples are recorded for 2θ values between 10° and 80° at 2°/min using Philips diffractometer with Cu Kα radiation.

2.3. Measurement of density

The densities (ρ) of all the glasses are determined using the Archimedes method with xylene (ρ = 0.863 g/cm³) as an immersion fluid. The density of glass calculated according to the formula:

$$\rho = \frac{W_A}{W_A - W_X} \times 0.863 \text{ g/cm}^3 \quad (1)$$

where W_A is the weight of the sample in air, W_X is the weight of the sample in xylene.

The molar volume V_m was calculated from molecular weight M and density ρ according to $V_m = M/\rho$ cm³/mol.

2.4. Differential scanning calorimetry (DSC)

DSC studies were carried out using Mettler Toledo DSC Star[®] System in 50–550 °C temperature range at the rate of 10 °C/min. For this, typically about 15–20 mg of a sample in a platelet form was hermetically sealed in aluminum pans and placed in the head of the calorimeter along with a reference pan.

2.5. Refractive index

The refractive index of glass samples have been measured using a Portable Jewel Refractometer (Chlight Corporation China Model CL – 1.30 to 1.80) with sodium D-Line (589 nm) as source of radiation.

2.6. Electron paramagnetic resonance

The EPR spectra of crushed samples were recorded at room temperature on an EPR spectrometer (BRUKER) operating in the X-band frequencies (9.305 GHz) with a modulation frequency of 100 kHz. The resonance line of DPPH with $g = 2.0036$ was used as a field marker.

2.7. Optical absorption

The optical absorption spectra of the prepared samples were recorded at room temperature using a Perkin-Elmer UV–vis spectrometer in the wavelength range 300–900 nm.

2.8. Infrared spectra

The IR spectra of the glasses were recorded at room temperature using Perkin-Elmer Spectrum GX using the KBr pellet disc method in the range 400–4000 cm^{−1}. Approximately 0.1–1.0% sample is well mixed into 200–250 mg fine KBr (alkali halide) powder and then finely pulverized and put into a pellet-forming die. A force of approximately 8 tons is applied under a vacuum of several mm Hg for several minutes form transparent pellets. Degassing is performed to eliminate air and moisture from the KBr powder. Inadequate vacuum may result in easily broken pellets that scatter light. Before forming the KBr powder into pellets, pulverize it to 200 mesh max and then dry at approximately 110 °C for 2–3 h. When performing measurements, the background can be measured with an empty pellet holder inserted into the sample chamber. However, background measurements on a pellet holder with a pellet of KBr only, that contains no sample, can correct for infrared light scattering losses in the pellet and for moisture adsorbed on the KBr.

3. Results and discussion

Phosphate glasses are low melting temperature glasses (~1000 °C). Visual inspection of crucible shows no chemical reaction between the melt and the crucible. UV–visible absorption spectra observed for all V₂O₅ doped samples show well defined absorption bands which are consistent with literature. Further, porcelain crucibles are recommended for phosphate glasses as it is known that phosphate melt reacts with the Platinum Crucible.

3.1. Powder X-ray diffraction studies

The X-ray diffraction pattern consists of a few broad peaks rather than sharp peaks, which is a sign of glassy material. All the prepared glass samples confirm the glassy nature. Fig. 1 shows the typical X-ray diffraction pattern of V1 glass sample.

Fig. 1. X-ray diffraction pattern of a V1 glass sample.

13	Thermal stability factor (°C) (± 1)	> 193	> 187	> 184	> 180	> 176	> 173

3.2. Physical properties

The mean atomic volume (V_M) of each glass was obtained from the values of densities (ρ) and mean atomic weights. The number of vanadyl ions per cm³ (N) was calculated from the glass composition and its density value. The calculated values are given in Table 2, along with other physical parameters.

The dielectric constant (ϵ) was calculated from the refractive index of the glass using [13].

$$\epsilon = n_d^2 \quad (2)$$

The reflection loss from the glass surface was computed from the refractive index by using Fresnel's formula as [14]

$$R = \left(\frac{n_d - 1}{n_d + 1} \right)^2 \quad (3)$$

The molar refractivity R_M for each glass was evaluated using [15]

$$R_M = \left(\frac{n_d^2 - 1}{n_d^2 + 2} \right) \frac{M}{\rho} \quad (4)$$

where M is the average molecular weight and ρ is the density in gm/cm³.

The electronic polarizability α_e was calculated using the formula [16]

$$\alpha_e = \frac{3(n_d^2 - 1)}{4\pi N(n_d^2 + 2)} \quad (5)$$

where N is the number of vanadyl ions per unit volume.

The polaron radius and inter-ionic separation were calculated using the formulae [17]

$$r_p = \frac{1}{2} \left(\frac{\pi}{6N} \right)^{1/3} \quad (6)$$

and

$$r_i = \left(\frac{1}{N} \right)^{1/3} \quad (7)$$

Density, refractive index, molar refractivity, ionic concentration, electronic polarizability, polaron radii and inter-ionic distances are evaluated. Density is found to increase while molar volume decreases with increasing substitution of V₂O₅ for P₂O₅. Since V₂O₅ has high molecular mass, therefore, it is an expected result. It can be noted from Table 2, the electronic polarizability decreases with the increase in V₂O₅ concentration, that is as the vanadyl ion concentration increases with increasing in V₂O₅ concentration. The contribution of ionic polarizability and orientation

Fig. 2. DSC trace of V₂ glass.

polarizability is expected to be marginal. Since most of the bonds involved are covalent type [18].

3.3. Differential scanning calorimeter

From the DSC pattern, the values of glass transition temperature (T_g) and thermal stability factor (S) presented in Table 2. In Fig. 2 typical DSC thermogram of V₂ glass is shown. The variation of glass transition temperature (T_g) with V₂O₅ content (V₂O₅) is presented in Fig. 3. Generally, the difference between crystallization temperature (T_c) and glass transition temperature (T_g), i.e., ($T_c - T_g$) gives a measure of thermal stability of a supercooled liquid (glass). The larger value of S , the stronger is the inhibition to nucleation and crystallization processes, and consequently, the better thermal stability of supercooled liquids (glass) [19]. T_c could not be identified in the present work in all samples; due to limitation DSC operating system as maximum temperature that could be attained is 550 °C. The stability factor of glasses investigated is in the range of 173–193 °C indicates glasses are stable against devitrification.

3.4. Electron paramagnetic resonance

Vanadium ions could be in V⁴⁺ and V⁵⁺ states in the P₂O₅–BaO–Li₂O glasses. During the melting of the glasses at higher

Fig. 3. Glass transition temperature vs. mol% of V_2O_5 contents of V-series glass system.

temperatures, there is a possibility for the following redox equilibrium to take place:

Normally, one considers the ratio V^{4+}/V_{total} lies in the range of 0.5–0.75 in the vanadate glasses and it increases with increasing V_2O_5 . The V_2O_5 content of our samples are low, and this implies that ratio is about 0.5.

To establish the presence of V^{4+} ions in the present glasses, we have recorded EPR and optical absorption spectra at the room temperature. EPR spectra show resolved hyperfine components arising from unpaired $3d^1$ electron with ^{51}V isotope ($I=7/2$, 100% abundance) and that they are very similar to those of the vanadyl ion, VO^{2+} , which is known to accure in glasses doped with vanadium oxide. Although V^{4+} ion is usually 6-fold coordinated its local symmetry is generally not octahedral, but axially distorted to a tetragonal symmetry (C_{4v}). This axial distortion of the octahedral is mainly responsible for the observed variation of the spectral parameters.

The EPR exhibit a well resolved typical hyperfine split spectrum due to ^{51}V ($I=7/2$) as shown in Fig. 4. The spectrum is interpreted using axially symmetric spin Hamiltonian [20].

$$H = \beta g_{\parallel} H_z S_z + \beta g_{\perp} (H_x S_x + H_y S_y) + A_{\parallel} S_z I_z + A_{\perp} (S_x I_x + S_y I_y) \quad (8)$$

where β is the Bohr magneton while $g_{\parallel}$, $g_{\perp}$ and $A_{\parallel}$, $A_{\perp}$ are the components of the gyromagnetic tensor g and hyperfine structure tensor A , respectively. H_x , H_y and H_z are components of magnetic field, S_x , S_y and S_z and I_x , I_y and I_z are the components of the spin operators of the electron and the nucleus, respectively.

The magnetic field positions of the parallel and perpendicular hyperfine peaks taking into account the second order perturbation terms, are given by following equations [21]

$$H_{\parallel}(m) = H_{\parallel}(0) - A_{\parallel} m - \frac{A_{\perp}^2}{2H_{\parallel}(0)} \left(\frac{63}{4} - m^2 \right) \quad (9)$$

$$H_{\perp}(m) = H_{\perp}(0) - A_{\perp} m - \frac{(A_{\parallel}^2 + A_{\perp}^2)}{4H_{\perp}(0)} \left(\frac{63}{4} - m^2 \right) \quad (10)$$

where m is the magnetic quantum number of the vanadium nucleus, which takes the values $\pm \frac{7}{2}$, $\pm \frac{5}{2}$, $\pm \frac{3}{2}$ and $\pm \frac{1}{2}$. $H_{\parallel}$ and $H_{\perp}$ are given by $H_{\parallel}(0) = \frac{h\nu}{g_{\parallel}\beta}$ and $H_{\perp}(0) = \frac{h\nu}{g_{\perp}\beta}$, where β is the Bohr magneton, ν is the spectrometer frequency.

The first approximation to $H_{\parallel}(0)$ and $H_{\perp}(0)$ were taken as the positions at which $m=0$ on a plotted curve of the experimentally observed lines vs. m . Thus, we may find a first approximation to the second-order terms $\frac{A_{\perp}^2}{2H_{\parallel}(0)}$ and $\frac{(A_{\parallel}^2 + A_{\perp}^2)}{4H_{\perp}(0)}$.

Fig. 4. EPR spectra of powder samples of VO^{2+} doped glass systems V5 and V6 at room temperature.

The spin Hamiltonian parameters $g_{\parallel}$, $g_{\perp}$ and $A_{\parallel}$, $A_{\perp}$ have been evaluated using the method given by Muncaster and Parke [21], and are listed in Table 3.

The spin-Hamiltonian parameters calculated for different mol% V_2O_5 doped phosphate barium lithium glasses are typical of vanadyl ions [$g_{\parallel}=1.8971$, $g_{\perp}=1.9608$, $A_{\parallel}=199.1257 \times 10^{-4} \text{ cm}^{-1}$ and $A_{\perp}=75.9261 \times 10^{-4} \text{ cm}^{-1}$]. Hecht and Johnston [22] extensively studied the EPR and optical absorption spectra of V^{4+} ions in soda-boric oxide glasses and found that there are two possibilities either three-fold or four-fold symmetry to describe the crystal field of V^{4+} ions in glasses. A detailed analysis of the g tensor in the presence of trigonal symmetry was given by Gladney and Swalen [23]. An octahedral site with a tetragonal compression would give $g_{\parallel} < g_{\perp} < g_e$ and $A_{\parallel} > A_{\perp}$ [24,25]. The g and A values obtained in the present work agree with this relationship and are close to those vanadyl complexes as reported by others [26–29]. It is therefore confirmed that the vanadyl ions in phosphate barium lithium glasses exist as VO^{2+} ions in octahedral coordination with a tetragonal compression and have C_{4v} symmetry. A pictorial representation of the axially distorted tetragonal symmetry (C_{4v}) is shown in Fig. 5. The bonding of the vanadyl ion in ligand field of octahedral symmetry has been well characterized by earlier workers [23,27]. The V^{4+} site in the VO^{2+} ion forms coplanar bonds with each of the four oxygen ligands. The vanadyl oxygen is attached axially above the V^{4+} site along the z -axis while the sixth oxygen forming the octahedral $O \cdot VO_4 \cdot O$ unit lies axially below the V^{4+} site.

The values of $\Delta g_{\parallel}$ and $\Delta g_{\perp}$ are evaluated using the relation $\Delta g_{\parallel} = g_e - g_{\parallel}$; $\Delta g_{\perp} = g_e - g_{\perp}$ which measures the tetragonality of the VO^{2+} and $g_e (= 2.0023)$ is the g factor of free electrons. The values of $\Delta g_{\parallel}$, $\Delta g_{\perp}$ and $\Delta g_{\parallel}/\Delta g_{\perp}$ obtained for the glasses containing different concentration of V_2O_5 are presented in Table 3; the ratio is observed to decrease gradually with increase in the concentration of V_2O_5 for the given series of glasses. This implies that as the concentration increases show that the octahedral symmetry around VO^{2+} ions is improved.

Using EPR and optical parameters, the molecular bonding coefficient β_1^2 and ϵ_{π}^2 are evaluated using the following formulae [30]:

$$\beta_1^2 = \frac{(g_e - g_{\parallel})\Delta_{\parallel}}{8\lambda\beta_2^2} \quad (11)$$

Fig. 5. A pictorial representation of the axially distorted tetragonal symmetry (C_{4v}).

Fig. 6. Optical absorption spectra of V-series glasses.

Table 3. From the optical absorption spectra (Fig. 6), a small change in band maxima due to small structural change in the glass matrix with increase in V₂O₅ content is observed. The bands in agreement with a C_{4v} local symmetry of isolated vanadium ions. The values β_1^2 and ϵ_{π}^2 are obtained from EPR and optical absorption data are consistent in the present investigation.

3.5. Optical absorption

The free ion ground state of VO²⁺ ion (d^1) is 2D . In a V–O crystal field of octahedral (O_h) symmetry, the d^1 electron occupies the lower t_2 orbital and gives rise to the 2T_2 ground state. In the excited state, the electron occupies the upper e orbital and gives rise to 2E state [32]. However, in general, the non-symmetrical alignment of the V–O bond along the symmetry axis lowers its symmetry from O_h to C_{4v} [33]. In a tetragonal crystal field (C_{4v}), the 2T_2 level splits into 2B_2 and 2E and 2E splits into 2B_1 and 2A_1 . Thus for V⁴⁺ ion in tetragonal symmetry, one can expect three bands corresponding to the $^2B_2 \rightarrow ^2E$, $^2B_2 \rightarrow ^2B_1$ and $^2B_2 \rightarrow ^2A_1$ transitions [34,35]. The general ordering of these energy levels is as follows: $^2B_2 < ^2E < ^2B_1 < ^2A_1$. Optical absorption spectra of VO²⁺ doped V-series glasses are shown in Fig. 5. The three characteristic bands suggest that the distortion around the vanadyl ion can be attributed to tetragonally compressed octahedral site. The bands are attributed to the $^2B_2 \rightarrow ^2E$, $^2B_2 \rightarrow ^2B_1$ and $^2B_2 \rightarrow ^2A_1$ transitions. Positions and sequence of the bands in the optical spectrum in Fig. 5 is as follows: the very broad band at higher wavelength is a resulting of two bands. The first band (780 nm) is attributed to $^2B_2 \rightarrow ^2E$ transition and the second one (670 nm) is related to $^2B_2 \rightarrow ^2B_1$ transition. The third band in decreasing wavelength direction corresponds to $^2B_2 \rightarrow ^2A_1$ (470 nm). There is a noticeable shifting of the $^2B_2 \rightarrow ^2E$ and $^2B_2 \rightarrow ^2B_1$ bands towards higher wavelength side with a gradual hike in the intensity with increase in the concentration of V₂O₅. This observation clearly suggest that an increasing the presence of vanadyl ions with increase in the concentration of V₂O₅ in the glass system.

3.6. Infrared spectra

It is well known that PO₄ tetrahedra are the basic structural units in phosphate glasses. The tetrahedral units are described by the Q^n notation, where “ n ” represents the number of bridging oxygens (BOs) that link neighboring P-tetrahedra [36]. Vitreous P₂O₅ structure has Q³ P-tetrahedra with three BOs and one double bonded oxygen P=O, forming a three-dimensional cross-linked network. Ultraphosphate glasses have both Q³ and Q² P-tetrahedra structural units. Metaphosphate glasses have Q² P-tetrahedra with two terminal oxygens that are shared with the modifying cation polyhedra. The Q² tetrahedra link to form long chains (or rings). Phosphate glasses based on pyrophosphate (Q¹) and orthophosphate (Q⁰) are also possible [37]. Van Wazer developed relationships that describe the compositional dependencies of the tetrahedral site distributions in binary alkali phosphate glasses [38]. The addition of a modifying oxide (R_2O) to phosphate glass

$$\epsilon_{\pi}^2 = \frac{(g_{\parallel} - g_{\perp})\Delta_{\perp}}{2\lambda\beta_2^2} \quad (12)$$

where β_1^2 and ϵ_{π}^2 are the degrees of the in-plane V–O σ -bonds and of π -bonding with the vanadyl oxygen. $\Delta_{||}$ and $\Delta_{\perp}$ are the energies of the electronic transitions $^2B_2 \rightarrow ^2B_1$ and $^2B_2 \rightarrow ^2E$, respectively. The free ion value of spin-orbit coupling constant for VO²⁺ is $\lambda = 170 \text{ cm}^{-1}$ and β_2^2 is assumed to be equal to 1 for the in-plane π -bonding with the equilateral ligands [31]. Using Eqs. (11) and (12) the values of β_1^2 and ϵ_{π}^2 were calculated and are given in

Fig. 7. Infrared transmission spectra of V series glasses.

depolymerizes the structure from ones with more highly cross-linked tetrahedra to ones with more non-bridging oxygens [NBOs] to maintain charge balance [38] which can be represented using relations,

Infrared spectra of the glass samples are shown in Fig. 7. The characteristic features are the (PO_2) asymmetric stretching vibration band at 1263 cm^{-1} ($\nu_{as} PO_2$), the (PO_2) symmetric stretching vibration band at 1090 cm^{-1} ($\nu_s PO_2$), $V=O$ vibration band at 1025 cm^{-1} , the (POP) asymmetric stretching vibration band at 894 cm^{-1} ($\nu_{as} POP$), $(V-O-P)$ vibration band at 765 cm^{-1} , the (POP) symmetric stretching vibration band at 738 cm^{-1} ($\nu_s POP$) [39–42]. The band located at 550 cm^{-1} is assigned to bending vibration of $O-P-O$ linkages. In this glass system vanadium content is $\leq 3\text{ mol\%}$, therefore bands showed no shift. $(V-O-P)$ band is observed when V_2O_5 concentration $> 1.5\text{ mol\%}$ [43].

4. Conclusions

Optical absorption spectra of the glass samples exhibits three absorption bands at 780, 670 and 470 nm are corresponding to $^2B_2 \rightarrow ^2E$, $^2B_2 \rightarrow ^2B_1$ and $^2B_2 \rightarrow ^2A_1$ transitions. The IR spectrum exhibits few bands, which are attributed to $(P=O)$, $(P-O)$, $(V=O)$ $(P-O-P)$, $P-O-V$, $(P-O-P)$ and $O-P-O$ group vibrations respectively. The EPR results show that $g_{||} < g_{\perp} < g_e(2.0023)$ and $A_{||} > A_{\perp}$ for all glass samples studied in the present work. Therefore, it is confirmed that V^{4+} ions in these samples exist as VO^{2+} ions in tetragonally compressed octahedral site and belong to C_{4v} symmetry. The spin-Hamiltonian parameters g and A are found to be independent of V_2O_5 content. Decrease in $\Delta g_{||}/\Delta g_{\perp}$ show that the octahedral symmetry around VO^{2+} ions is improved.
